Thrust (fuel flow) is controlled primarily by a hydro-mechanical MEC in response to thrust lever movement, as fitted to the original 737-1/200's. In the -3/4/500 series, fuel flow is further refined electronically by the PMC, which acts without thrust lever movement. The 737-NG models go one stage further with FADEC (EEC).

The 737-700 performed flight maneuvers as predicted and met or exceeded performance expectations for simulated one-engine-inoperative maneuvers, which were accomplished by reducing thrust on one engine to idle power. The expected performance levels proved conservative when compared with the demonstrated performance of the 737-700.

The Boeing 737 MAX is the fourth generation of the Boeing 737, a narrow-body airliner manufactured by Boeing Commercial Airplanes (BCA). It succeeds the Boeing 737 Next Generation (NG). It is based on earlier 737 designs, with more efficient CFM International LEAP-1B engines, aerodynamic changes including its distinctive split-tip winglets, and airframe modifications.

The air that's passing by the core of the engine is giving most of the thrust and that also has the benefits of damping the sounds. Hence, they are much more fuel-efficient and quieter than the turbojet engines. The Boeing engineers wanted to fit the new CFM56 engines onto the 737 model but here they encountered a

This Is Why The Engines Of Boeing 737 Are Kept Flat

A "thrust reverser" is a part of the engine of a plane. It changes the flow of air through the engine so that it ends up trying to push the plane backwards instead of forwards. The first thrust reversers on the 737 were not very good. They were said to lift the aircraft off the runway when they were used.

The reasons given by Boeing, for re-fitting the 737 with increased thrust fan engines, not designed for this particular aircraft, in my opinion, was totally irrational. Two of the reasons given: were directed at the crews that service the aircraft, and the ability of passengers to enter or exit the aircraft.
